## Defective Design of the Remington Model 700 Rifle

A 10-month investigation by CNBC has found that at least two dozen deaths and more than 100 injuries have been linked to the signature product of an iconic American company.

The Model 700 rifle suffers from a serious design defect, sometimes compounded by manufacturing defects that causes the rifle to fire without pulling the trigger. The source of the defect is an internal component in the trigger mechanism called the "trigger connector." The trigger connector is what allows the gun to fire once the trigger has been pulled. This system is known as the Walker Fire Control System and Remington is the only gun manufacturer in the world to use it.

The problem with the trigger connector is that the resiliently mounted trigger connector is not bound to the actual trigger. This means that when the trigger is pulled and the gun is fired, a gap is created between the trigger body and the connector. **Dirt, debris, dried lubricant and other material then can become lodged in this gap, preventing the trigger connector from returning to a secure and reliable position after the gun is fired.** This, in turn, can permit the fire control to malfunction to produce a discharge when the trigger is **not** pulled.

The three most common scenarios for the fire control to malfunction are:

- When the user moves the safety switch from the "safe" mode to the "fire" mode
- When the user loads a new round into the breech (Fire closing the bolt)
- When the user cycles the bolt to eject a spent casing (Fire opening the bolt)
