

Firing Pin Protrusion and Indentation

A measure of both indentation and protrusion was obtained at nine regular intervals during the test.

The results indicate the main spring and cocking cam, firing pin and retaining wedge to be very satisfactory from a standpoint of material, heat treatment, workmanship and design. The parts involved are identical for both the M/721 and 722.

There was no significant change in either firing pin protrusion or indentation during the test:

	<u>Indentation</u>	<u>Protrusion</u>
M/721 - 300 H & H Magnum		
Initial Test	0.020"	0.053"
Final Test	0.021"	0.055"
